Glib::Param::GType(3pm)      User Contributed Perl Documentation      Glib::Param::GType(3pm)

NAME

Glib::Param::GType - Wrapper for type parameters in GLib

HIERARCHY

Glib::ParamSpec

+----Glib::Param::GType

DESCRIPTION

This object describes a parameter which holds the name of a class known to the GLib type system. The name of the class is considered to be the common ancestor for valid values.

To create a param that allows any type name, specify "undef" for the package name.

Beware, however, that although we say "any type name", this actually refers to any type registered with Glib; normal Perl packages will not work.

METHODS

string or undef = \$spec\_gtype->get\_is\_a\_type

If "undef", then any class is allowed.

Since: glib 2.10

Glib, Glib::ParamSpec
