C:\>man Dpkg::Path.3perl

Dpkg::Path(3perl) libdpkg-perl Dpkg::Path(3perl)

NAME

Dpkg::Path - some common path handling functions

DESCRIPTION

It provides some functions to handle various path.

FUNCTIONS

get_pkg_root_dir(\$file)

This function will scan upwards the hierarchy of directory to find out the directory which contains the "DEBIAN" sub-directory and it will return its path. This directory is the root directory of a package being built.

If no DEBIAN subdirectory is found, it will return undef.

relative_to_pkg_root(\$file)

Returns the filename relative to get_pkg_root_dir(\$file).

guess_pkg_root_dir(\$file)

This function tries to guess the root directory of the package build tree.

It will first use get_pkg_root_dir(), but it will fallback to a more imprecise check: namely it will use the parent directory that is a sub-directory of the debian directory.

It can still return undef if a file outside of the debian sub-directory is provided.

check_files_are_the_same(\$file1, \$file2, \$resolve_symlink)

This function verifies that both files are the same by checking that the

device numbers and the inode numbers returned by `stat()/lstat()` are the same. If `$resolve_symlink` is true then `stat()` is used, otherwise `lstat()` is used.

`canonpath($file)`

This function returns a cleaned path. It simplifies double `//`, and remove `./` and `../` intelligently. For `../` it simplifies the path only if the previous element is not a symlink. Thus it should only be used on real filenames.

`$newpath = resolve_symlink($symlink)`

Return the filename of the file pointed by the symlink. The new name is canonicalized by `canonpath()`.

`$cmdpath = find_command($command)`

Return the path of the command if defined and available on an absolute or relative path or on the `$PATH`, undef otherwise.

`$control_file = get_control_path($pkg, $filetype)`

Return the path of the control file of type `$filetype` for the given package.

`@control_files = get_control_path($pkg)`

Return the path of all available control files for the given package.

`$file = find_build_file($basename)`

Selects the right variant of the given file: the arch-specific variant ("`$basename.$arch`") has priority over the OS-specific variant ("`$basename.$os`") which has priority over the default variant ("`$basename`"). If none of the files exists, then it returns undef.

`@files = find_build_file($basename)`

Return the available variants of the given file. Returns an empty list if none of the files exists.

CHANGES

Version 1.04 (dpkg 1.17.11)

Update semantics: `find_command()` now handles an empty or undef argument.

Version 1.03 (dpkg 1.16.1)

New function: `find_build_file()`

Version 1.02 (dpkg 1.16.0)

New function: `get_control_path()`

Version 1.01 (dpkg 1.15.8)

New function: `find_command()`

Version 1.00 (dpkg 1.15.6)

Mark the module as public.

1.19.7
