SHM_OPEN(3) Linux Programmer's Manual SHM_OPEN(3)

NAME

shm_open, shm_unlink - create/open or unlink POSIX shared memory objects

SYNOPSIS

```
#include <sys/mman.h>
```

```
#include <sys/stat.h>       /* For mode constants */
```

```
#include <fcntl.h>         /* For O_* constants */
```

```
int shm_open(const char *name, int oflag, mode_t mode);
```

```
int shm_unlink(const char *name);
```

Link with -lrt.

DESCRIPTION

shm_open() creates and opens a new, or opens an existing, POSIX shared memory object. A POSIX shared memory object is in effect a handle which can be used by un? related processes to mmap(2) the same region of shared memory. The shm_unlink() function performs the converse operation, removing an object previously created by shm_open().

The operation of shm_open() is analogous to that of open(2). name specifies the shared memory object to be created or opened. For portable use, a shared memory object should be identified by a name of the form /somenam?; that is, a null-terminat? string of up to NAME_MAX (i.e., 255) characters consisting of an initial slash, followed by one or more characters, none of which are slashes.

oflag is a bit mask created by ORing together exactly one of O_RDONLY or O_RDWR and

any of the other flags listed here:

O_RDONLY Open the object for read access. A shared memory object opened in this way can be `mmap(2)`ed only for read (`PROT_READ`) access.

O_RDWR Open the object for read-write access.

O_CREAT Create the shared memory object if it does not exist. The user and group ownership of the object are taken from the corresponding effective IDs of the calling process, and the object's permission bits are set according to the low-order 9 bits of mode, except that those bits set in the process file mode creation mask (see `umask(2)`) are cleared for the new object. A set of macro constants which can be used to define mode is listed in `open(2)`. (Symbolic definitions of these constants can be obtained by including `<sys/stat.h>`.)

A new shared memory object initially has zero length?the size of the object can be set using `ftruncate(2)`. The newly allocated bytes of a shared memory object are automatically initialized to 0.

O_EXCL If `O_CREAT` was also specified, and a shared memory object with the given name already exists, return an error. The check for the existence of the object, and its creation if it does not exist, are performed atomically.

O_TRUNC If the shared memory object already exists, truncate it to zero bytes. Definitions of these flag values can be obtained by including `<fcntl.h>`.

On successful completion `shm_open()` returns a new file descriptor referring to the shared memory object. This file descriptor is guaranteed to be the lowest-numbered file descriptor not previously opened within the process. The `FD_CLOEXEC` flag (see `fcntl(2)`) is set for the file descriptor.

The file descriptor is normally used in subsequent calls to `ftruncate(2)` (for a newly created object) and `mmap(2)`. After a call to `mmap(2)` the file descriptor may be closed without affecting the memory mapping.

The operation of `shm_unlink()` is analogous to `unlink(2)`: it removes a shared memory object name, and, once all processes have unmapped the object, de-allocates and destroys the contents of the associated memory region. After a successful `shm_unlink()`, attempts to `shm_open()` an object with the same name fail (unless `O_CREAT` was specified, in which case a new, distinct object is created).

RETURN VALUE

On success, `shm_open()` returns a nonnegative file descriptor. On failure, `shm_open()` returns -1. `shm_unlink()` returns 0 on success, or -1 on error.

ERRORS

On failure, `errno` is set to indicate the cause of the error. Values which may appear in `errno` include the following:

EACCES Permission to `shm_unlink()` the shared memory object was denied.

EACCES Permission was denied to `shm_open()` name in the specified mode, or `O_TRUNC` was specified and the caller does not have write permission on the object.

EEXIST Both `O_CREAT` and `O_EXCL` were specified to `shm_open()` and the shared memory object specified by name already exists.

EINVAL The name argument to `shm_open()` was invalid.

EMFILE The per-process limit on the number of open file descriptors has been reached.

ENAMETOOLONG

The length of name exceeds `PATH_MAX`.

ENFILE The system-wide limit on the total number of open files has been reached.

ENOENT An attempt was made to `shm_open()` a name that did not exist, and `O_CREAT` was not specified.

ENOENT An attempt was to made to `shm_unlink()` a name that does not exist.

VERSIONS

These functions are provided in glibc 2.2 and later.

ATTRIBUTES

For an explanation of the terms used in this section, see `attributes(7)`.

CONFORMING TO

POSIX.1-2001, POSIX.1-2008.

POSIX.1-2001 says that the group ownership of a newly created shared memory object is set to either the calling process's effective group ID or "a system default

group ID". POSIX.1-2008 says that the group ownership may be set to either the calling process's effective group ID or, if the object is visible in the filesystem, the group ID of the parent directory.

NOTES

POSIX leaves the behavior of the combination of `O_RDONLY` and `O_TRUNC` unspecified.

On Linux, this will successfully truncate an existing shared memory object?this may not be so on other UNIX systems.

The POSIX shared memory object implementation on Linux makes use of a dedicated `tmpfs(5)` filesystem that is normally mounted under `/dev/shm`.
