BIO\_SHOULD\_RETRY(3ossl)      OpenSSL      BIO\_SHOULD\_RETRY(3ossl)

#### NAME

BIO\_should\_read, BIO\_should\_write, BIO\_should\_io\_special,  
BIO\_retry\_type, BIO\_should\_retry, BIO\_get\_retry\_BIO,  
BIO\_get\_retry\_reason, BIO\_set\_retry\_reason - BIO retry functions

#### SYNOPSIS

```
#include <openssl/bio.h>

int BIO_should_read(BIO *b);
int BIO_should_write(BIO *b);
int BIO_should_io_special(iBIO *b);
int BIO_retry_type(BIO *b);
int BIO_should_retry(BIO *b);
BIO *BIO_get_retry_BIO(BIO *bio, int *reason);
int BIO_get_retry_reason(BIO *bio);
void BIO_set_retry_reason(BIO *bio, int reason);
```

#### DESCRIPTION

These functions determine why a BIO is not able to read or write data.

They will typically be called after a failed BIO\_read\_ex() or

BIO\_write\_ex() call.

BIO\_should\_retry() is true if the call that produced this condition should then be retried at a later time.

If BIO\_should\_retry() is false then the cause is an error condition.

BIO\_should\_read() is true if the cause of the condition is that the BIO has insufficient data to return. Check for readability and/or retry the last operation.

BIO\_should\_write() is true if the cause of the condition is that the BIO has pending data to write. Check for writability and/or retry the last operation.

BIO\_should\_io\_special() is true if some "special" condition, that is a reason other than reading or writing is the cause of the condition.

BIO\_retry\_type() returns a mask of the cause of a retry condition consisting of the values BIO\_FLAGS\_READ, BIO\_FLAGS\_WRITE, BIO\_FLAGS\_IO\_SPECIAL though current BIO types will only set one of these.

BIO\_get\_retry\_BIO() determines the precise reason for the special condition, it returns the BIO that caused this condition and if reason is not NULL it contains the reason code. The meaning of the reason code and the action that should be taken depends on the type of BIO that resulted in this condition.

BIO\_get\_retry\_reason() returns the reason for a special condition if passed the relevant BIO, for example as returned by BIO\_get\_retry\_BIO().

BIO\_set\_retry\_reason() sets the retry reason for a special condition for a given BIO. This would usually only be called by BIO implementations.

## NOTES

BIO\_should\_read(), BIO\_should\_write(), BIO\_should\_io\_special(), BIO\_retry\_type(), and BIO\_should\_retry(), are implemented as macros.

If BIO\_should\_retry() returns false then the precise "error condition" depends on the BIO type that caused it and the return code of the BIO operation. For example if a call to BIO\_read\_ex() on a socket BIO

returns 0 and `BIO_should_retry()` is false then the cause will be that the connection closed. A similar condition on a file BIO will mean that it has reached EOF. Some BIO types may place additional information on the error queue. For more details see the individual BIO type manual pages.

If the underlying I/O structure is in a blocking mode almost all current BIO types will not request a retry, because the underlying I/O calls will not. If the application knows that the BIO type will never signal a retry then it need not call `BIO_should_retry()` after a failed BIO I/O call. This is typically done with file BIOs.

SSL BIOs are the only current exception to this rule: they can request a retry even if the underlying I/O structure is blocking, if a handshake occurs during a call to `BIO_read()`. An application can retry the failed call immediately or avoid this situation by setting `SSL_MODE_AUTO_RETRY` on the underlying SSL structure.

While an application may retry a failed non blocking call immediately this is likely to be very inefficient because the call will fail repeatedly until data can be processed or is available. An application will normally wait until the necessary condition is satisfied. How this is done depends on the underlying I/O structure.

For example if the cause is ultimately a socket and `BIO_should_read()` is true then a call to `select()` may be made to wait until data is available and then retry the BIO operation. By combining the retry conditions of several non blocking BIOs in a single `select()` call it is possible to service several BIOs in a single thread, though the performance may be poor if SSL BIOs are present because long delays can occur during the initial handshake process.

It is possible for a BIO to block indefinitely if the underlying I/O structure cannot process or return any data. This depends on the behaviour of the platforms I/O functions. This is often not desirable: one solution is to use non blocking I/O and use a timeout on the `select()` (or equivalent) call.

The OpenSSL ASN1 functions cannot gracefully deal with non blocking I/O: that is they cannot retry after a partial read or write. This is usually worked around by only passing the relevant data to ASN1 functions when the entire structure can be read or written.

## RETURN VALUES

BIO\_should\_read(), BIO\_should\_write(), BIO\_should\_io\_special(), and BIO\_should\_retry() return either 1 or 0 based on the actual conditions of the BIO.

BIO\_retry\_type() returns a flag combination presenting the cause of a retry condition or false if there is no retry condition.

BIO\_get\_retry\_BIO() returns a valid BIO structure.

BIO\_get\_retry\_reason() returns the reason for a special condition.

## SEE ALSO

bio(7)

## HISTORY

The BIO\_get\_retry\_reason() and BIO\_set\_retry\_reason() functions were added in OpenSSL 1.1.0.
