\$ man capset.2

capget(2) System Calls Manual capget(2)

NAME

capget, capset - set/get capabilities of thread(s)

LIBRARY

Standard C library (libc, -lc)

SYNOPSIS

```
#include <linux/capability.h> /* Definition of CAP_* and
                               _LINUX_CAPABILITY_* constants */

#include <sys/syscall.h>      /* Definition of SYS_* constants */

#include <unistd.h>

int syscall(SYS_capget, cap_user_header_t hdrp,
            cap_user_data_t datap);

int syscall(SYS_capset, cap_user_header_t hdrp,
            const cap_user_data_t datap);
```

Note: glibc provides no wrappers for these system calls, necessitating the use of syscall(2).

DESCRIPTION

These two system calls are the raw kernel interface for getting and setting thread capabilities. Not only are these system calls specific to Linux, but the kernel API is likely to change and use of these system calls (in particular the format of the cap_user_*_t types) is subject to extension with each kernel revision, but old programs will keep working.

The portable interfaces are cap_set_proc(3) and cap_get_proc(3); if possible, you should use those interfaces in applications; see NOTES.

Current details

Now that you have been warned, some current kernel details. The structures are defined as follows.

```
#define _LINUX_CAPABILITY_VERSION_1 0x19980330

#define _LINUX_CAPABILITY_U32S_1 1

/* V2 added in Linux 2.6.25; deprecated */

#define _LINUX_CAPABILITY_VERSION_2 0x20071026

#define _LINUX_CAPABILITY_U32S_2 2

/* V3 added in Linux 2.6.26 */

#define _LINUX_CAPABILITY_VERSION_3 0x20080522

#define _LINUX_CAPABILITY_U32S_3 3

typedef struct __user_cap_header_struct {
    __u32 version;

    int pid;
} *cap_user_header_t;

typedef struct __user_cap_data_struct {
    __u32 effective;

    __u32 permitted;

    __u32 inheritable;
} *cap_user_data_t;
```

The effective, permitted, and inheritable fields are bit masks of the capabilities defined in `capabilities(7)`. Note that the `CAP_*` values are bit indexes and need to be bit-shifted before ORing into the bit fields. To define the structures for passing to the system call, you have to use the struct `__user_cap_header_struct` and struct `__user_cap_data_struct` names because the typedefs are only pointers.

Kernels prior to Linux 2.6.25 prefer 32-bit capabilities with version `_LINUX_CAPABILITY_VERSION_1`. Linux 2.6.25 added 64-bit capability sets, with version `_LINUX_CAPABILITY_VERSION_2`. There was, however, an API glitch, and Linux 2.6.26 added `_LINUX_CAPABILITY_VERSION_3` to fix the problem.

Note that 64-bit capabilities use `datap[0]` and `datap[1]`, whereas 32-bit capabilities use only `datap[0]`.

On kernels that support file capabilities (VFS capabilities support), these system calls behave slightly differently. This support was added as an option in Linux 2.6.24, and became

fixed (nonoptional) in Linux 2.6.33.

For `capget()` calls, one can probe the capabilities of any process by specifying its process ID with the `hdrp->pid` field value.

For details on the data, see `capabilities(7)`.

With VFS capabilities support

VFS capabilities employ a file extended attribute (see `xattr(7)`) to allow capabilities to be attached to executables. This privilege model obsoletes kernel support for one process asynchronously setting the capabilities of another. That is, on kernels that have VFS capabilities support, when calling `capset()`, the only permitted values for `hdrp->pid` are 0 or, equivalently, the value returned by `gettid(2)`.

Without VFS capabilities support

On older kernels that do not provide VFS capabilities support `capset()` can, if the caller has the `CAP_SETPCAP` capability, be used to change not only the caller's own capabilities, but also the capabilities of other threads. The call operates on the capabilities of the thread specified by the `pid` field of `hdrp` when that is nonzero, or on the capabilities of the calling thread if `pid` is 0. If `pid` refers to a single-threaded process, then `pid` can be specified as a traditional process ID; operating on a thread of a multithreaded process requires a thread ID of the type returned by `gettid(2)`. For `capset()`, `pid` can also be: -1, meaning perform the change on all threads except the caller and `init(1)`; or a value less than -1, in which case the change is applied to all members of the process group whose ID is `-pid`.

RETURN VALUE

On success, zero is returned. On error, -1 is returned, and `errno` is set to indicate the error.

The calls fail with the error `EINVAL`, and set the version field of `hdrp` to the kernel preferred value of `_LINUX_CAPABILITY_VERSION_?` when an unsupported version value is specified.

In this way, one can probe what the current preferred capability revision is.

ERRORS

EFAULT Bad memory address. `hdrp` must not be NULL. `datap` may be NULL only when the user is trying to determine the preferred capability version format supported by the kernel.

EINVAL One of the arguments was invalid.

EPERM An attempt was made to add a capability to the permitted set, or to set a capability in the effective set that is not in the permitted set.

EPERM An attempt was made to add a capability to the inheritable set, and either:

- ? that capability was not in the caller's bounding set; or
- ? the capability was not in the caller's permitted set and the caller lacked the CAP_SETPCAP capability in its effective set.

EPERM The caller attempted to use `capset()` to modify the capabilities of a thread other than itself, but lacked sufficient privilege. For kernels supporting VFS capabilities, this is never permitted. For kernels lacking VFS support, the CAP_SETPCAP capability is required. (A bug in kernels before Linux 2.6.11 meant that this error could also occur if a thread without this capability tried to change its own capabilities by specifying the `pid` field as a nonzero value (i.e., the value returned by `getpid(2)`) instead of 0.)

ESRCH No such thread.

STANDARDS

Linux.

NOTES

The portable interface to the capability querying and setting functions is provided by the `libcap` library and is available here:
