

**NAME**

git-credential-cache--daemon – Temporarily store user credentials in memory

**SYNOPSIS**

git credential-cache—daemon [--debug] <socket>

**DESCRIPTION****Note**

You probably don't want to invoke this command yourself; it is started automatically when you use **git-credential-cache(1)**.

This command listens on the Unix domain socket specified by <socket> for **git-credential-cache** clients. Clients may store and retrieve credentials. Each credential is held for a timeout specified by the client; once no credentials are held, the daemon exits.

If the **--debug** option is specified, the daemon does not close its stderr stream, and may output extra diagnostics to it even after it has begun listening for clients.
